Bright background sources: a few options

QSOs

$$R_{\text{QSO}} \sim 10^{-3} \text{ pc}$$

Shakura & Sunyaev 1973
Frank+2007

Stars

$$R_B \sim 10^{-7} \text{ pc}$$

Galaxies

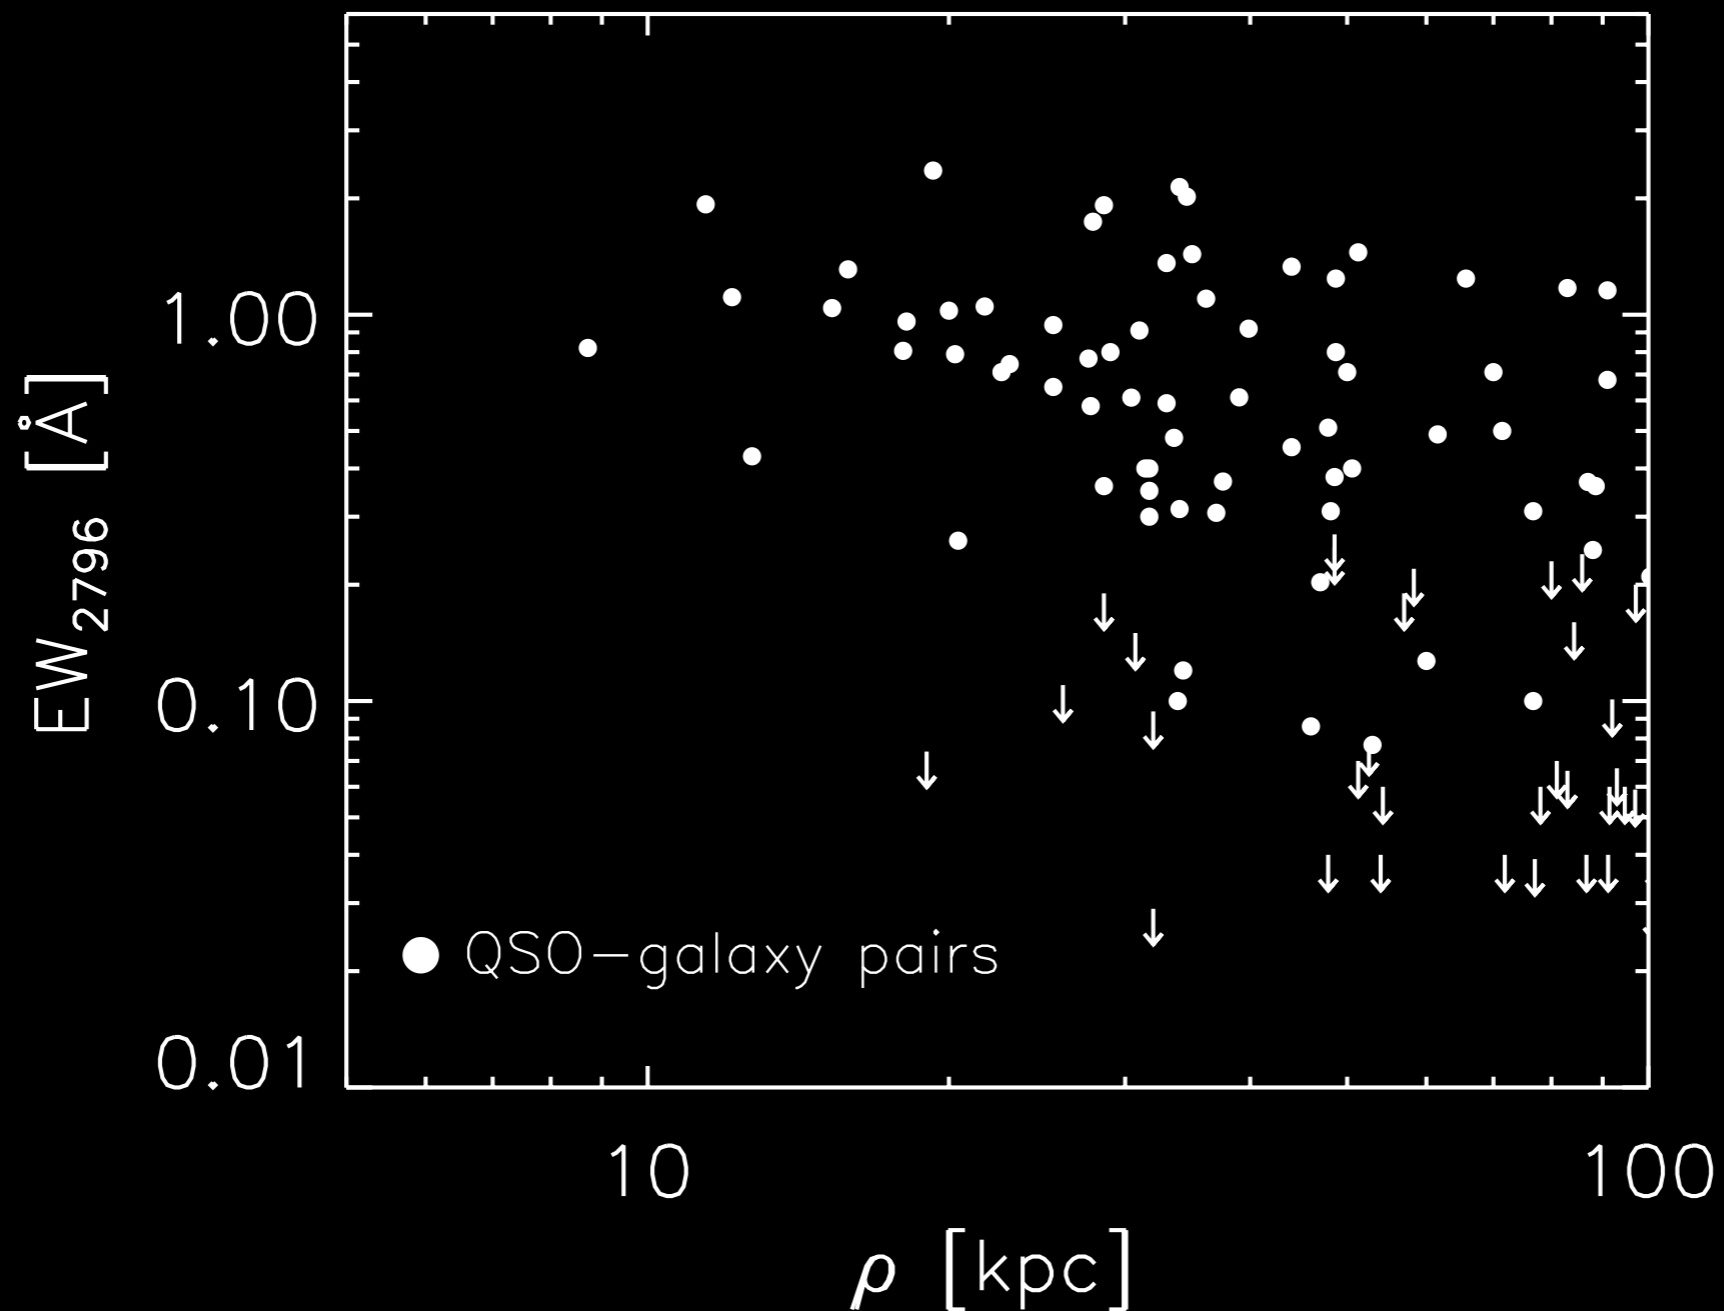

$$R_{\text{gal}} > 1 \text{ kpc}$$

at $z \sim 1$

Background QSO spectroscopy is 'easy'.

And at $z \sim 0.3-1$, MgII 2796, 2803 is the transition of choice.

Barton & Cooke 09,
Chen+10,
Werk+13

Background QSO spectroscopy is 'easy'.

And at $z \sim 0.3-1$, MgII 2796, 2803 is the transition of choice.

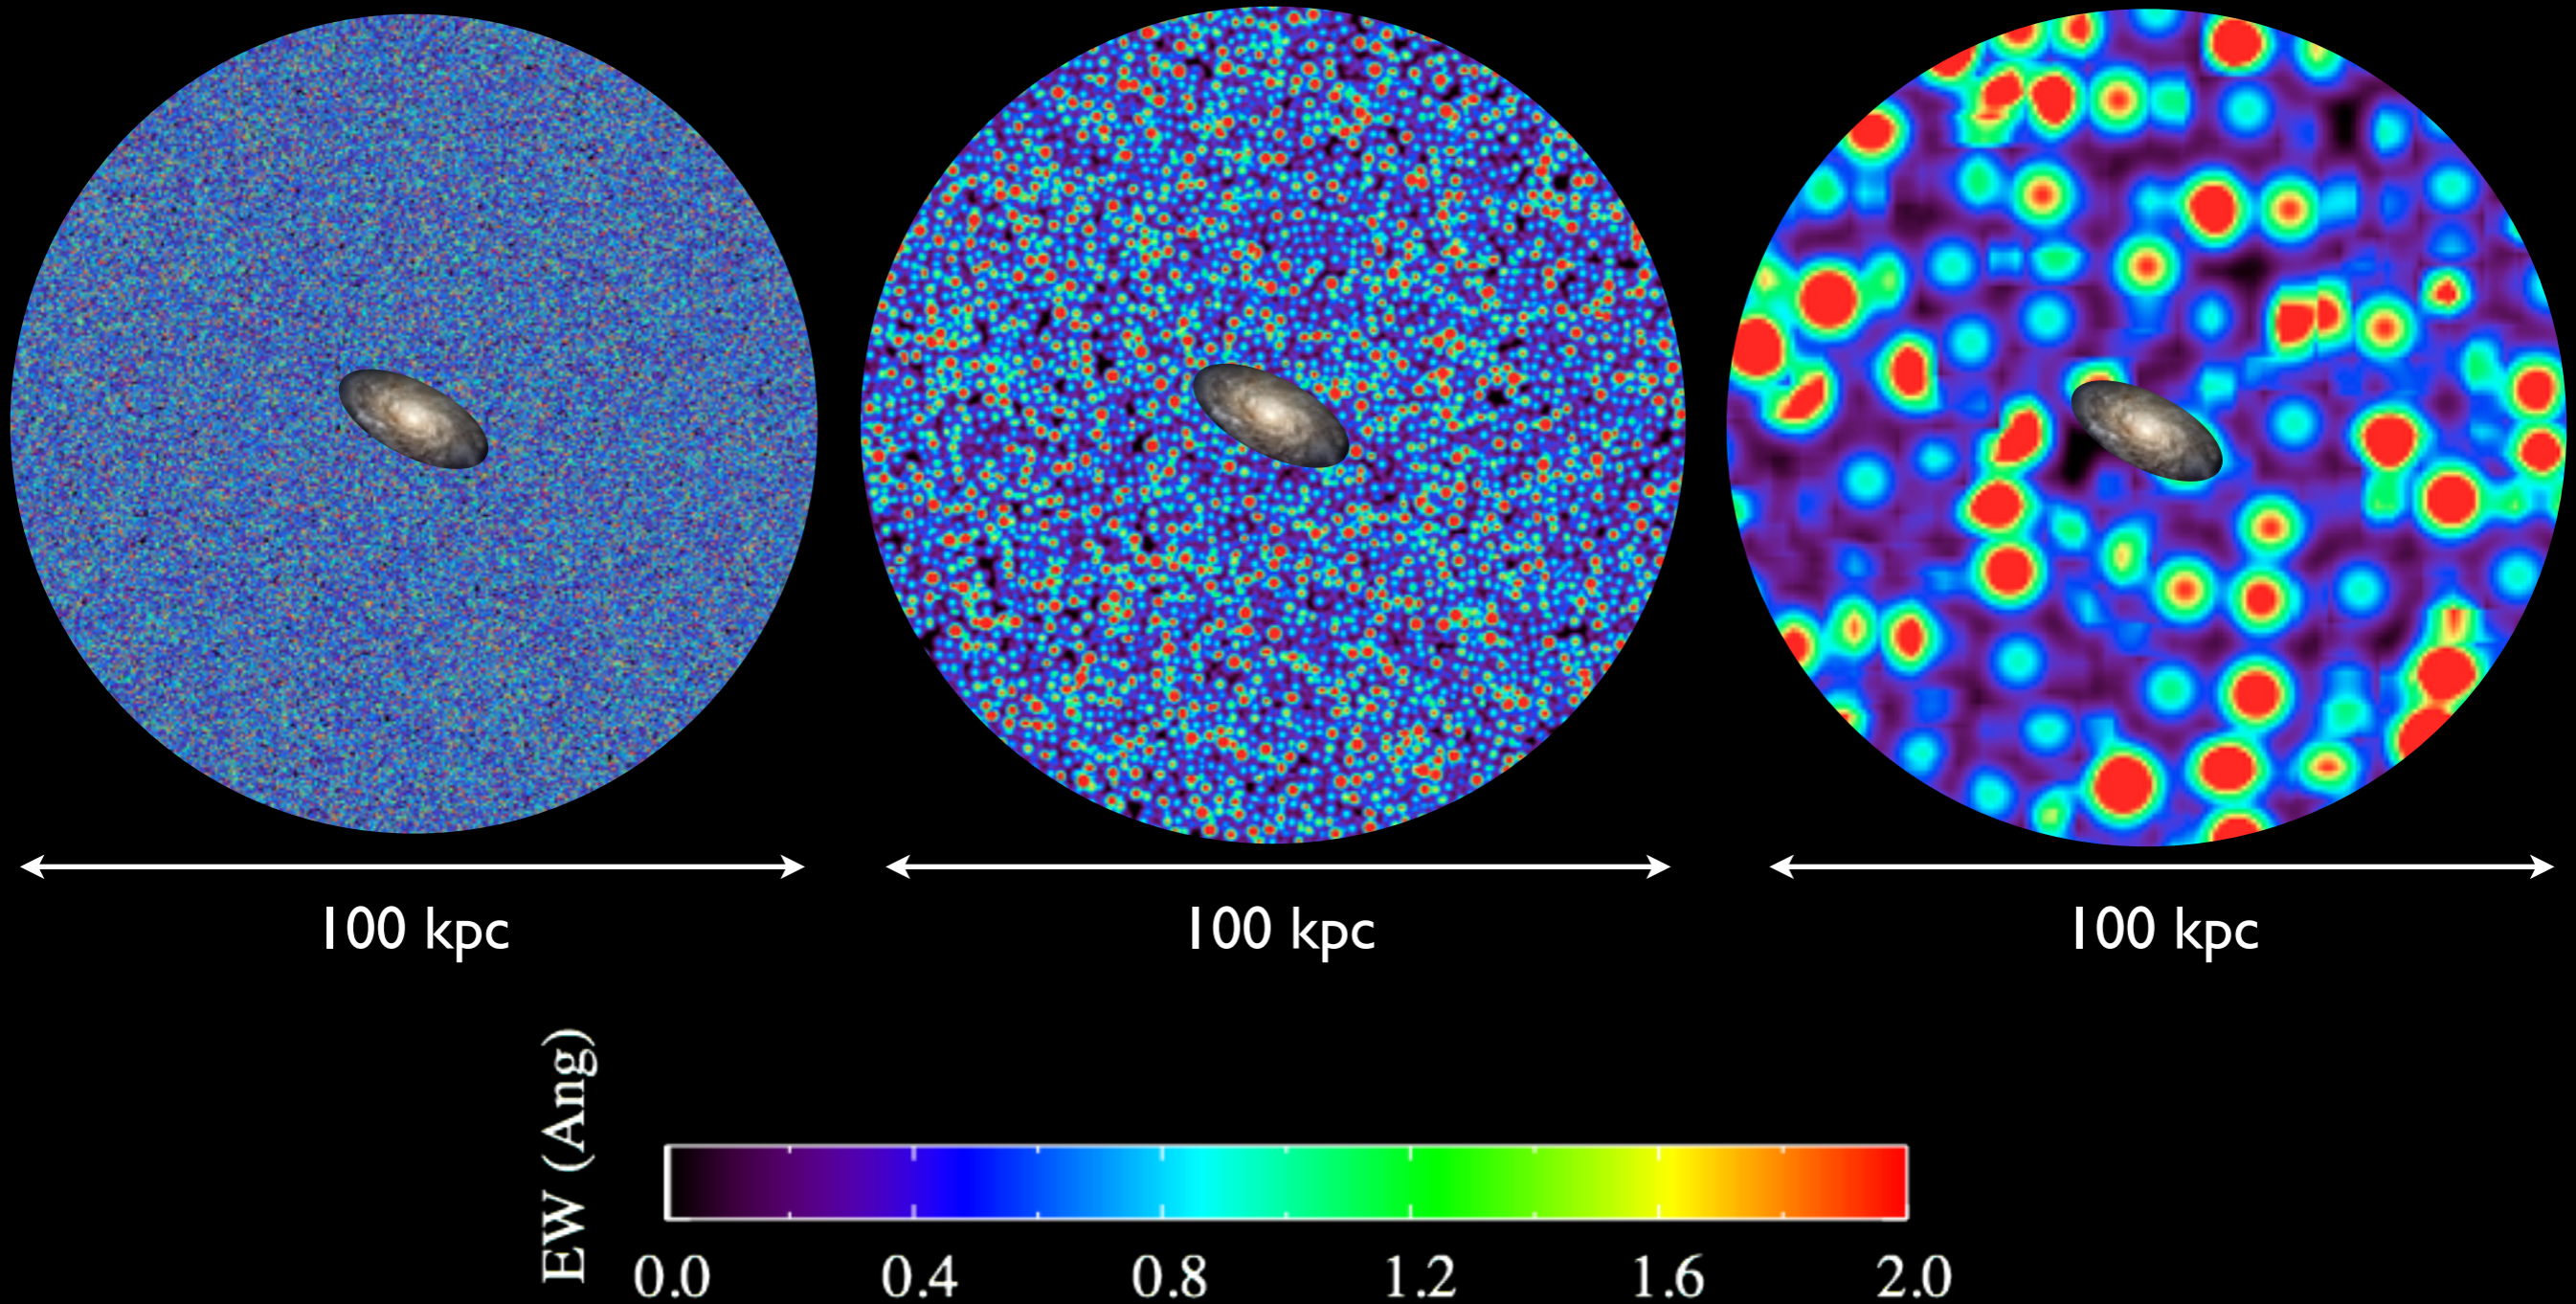

Background QSO spectroscopy is 'easy'.

And at $z \sim 0.3-1$, MgII 2796, 2803 is the transition of choice.

What picture does this paint?
(Recall: QSOs have $R_{\text{QSO}} \sim 10^{-3}$ pc)

So, all we need are:

- (1) Bright ($g < 22$) blue galaxies at $z \sim 0.3-1$
- (2) which are also within 50 kpc (projected) of a foreground galaxy

09:59:48.9
+02:03:27.9

LGP
720.0
6170
2.4

That is, we need PRIMUS: (a Magellan/IMACS redshift survey)

The PRIMUS Pairs:

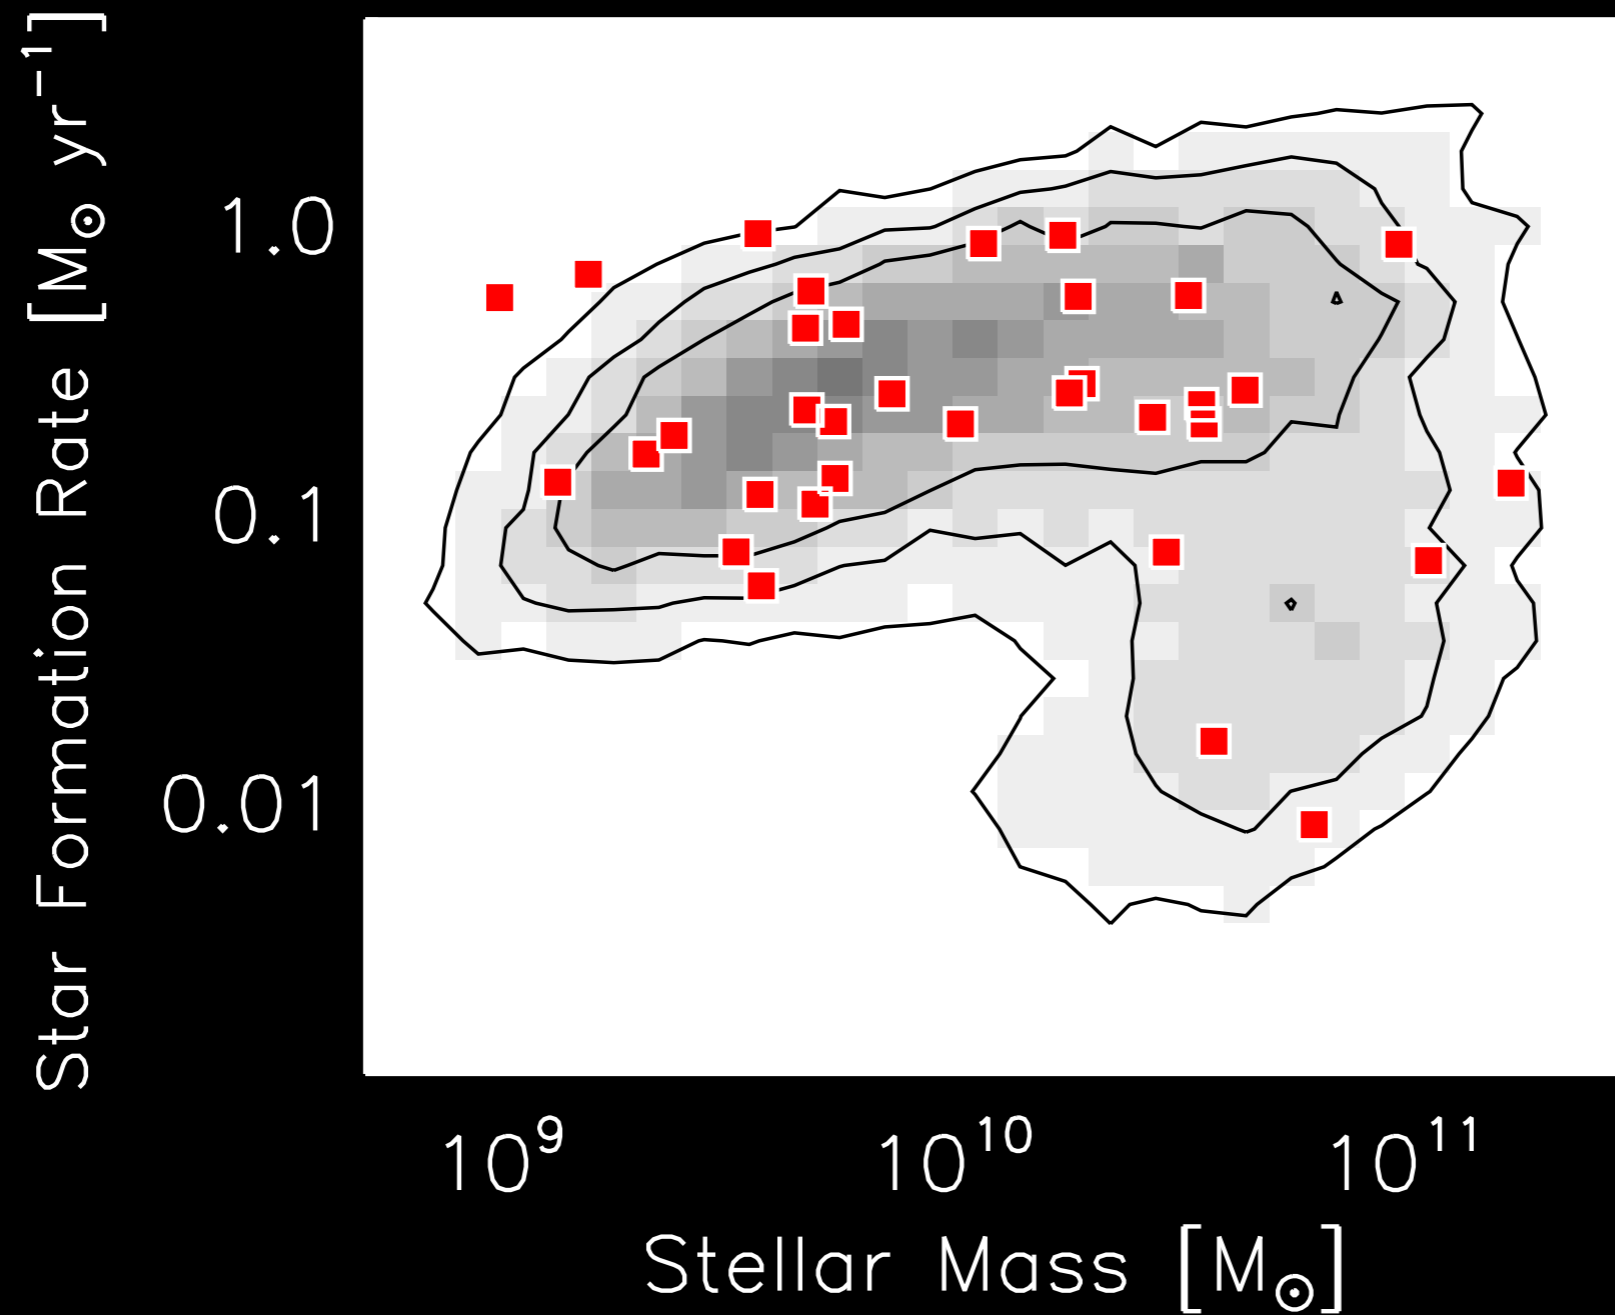

All projected pairs within 50 kpc with

— background objects having $g < 22.3$

— foreground objects having $r < 23$, $0.35 < z < 1.2$

The PRIMUS foreground galaxies:

The PRIMUS galaxy pair spectroscopy

~40 pairs observed over 9 nights on Keck/
LRIS and VLT/FORS2

180 - 300 km/s FWHM resolution

cover at least f/g MgII 2796, 2803, often
FeII 2586, 2600

The PRIMUS galaxy pair spectroscopy

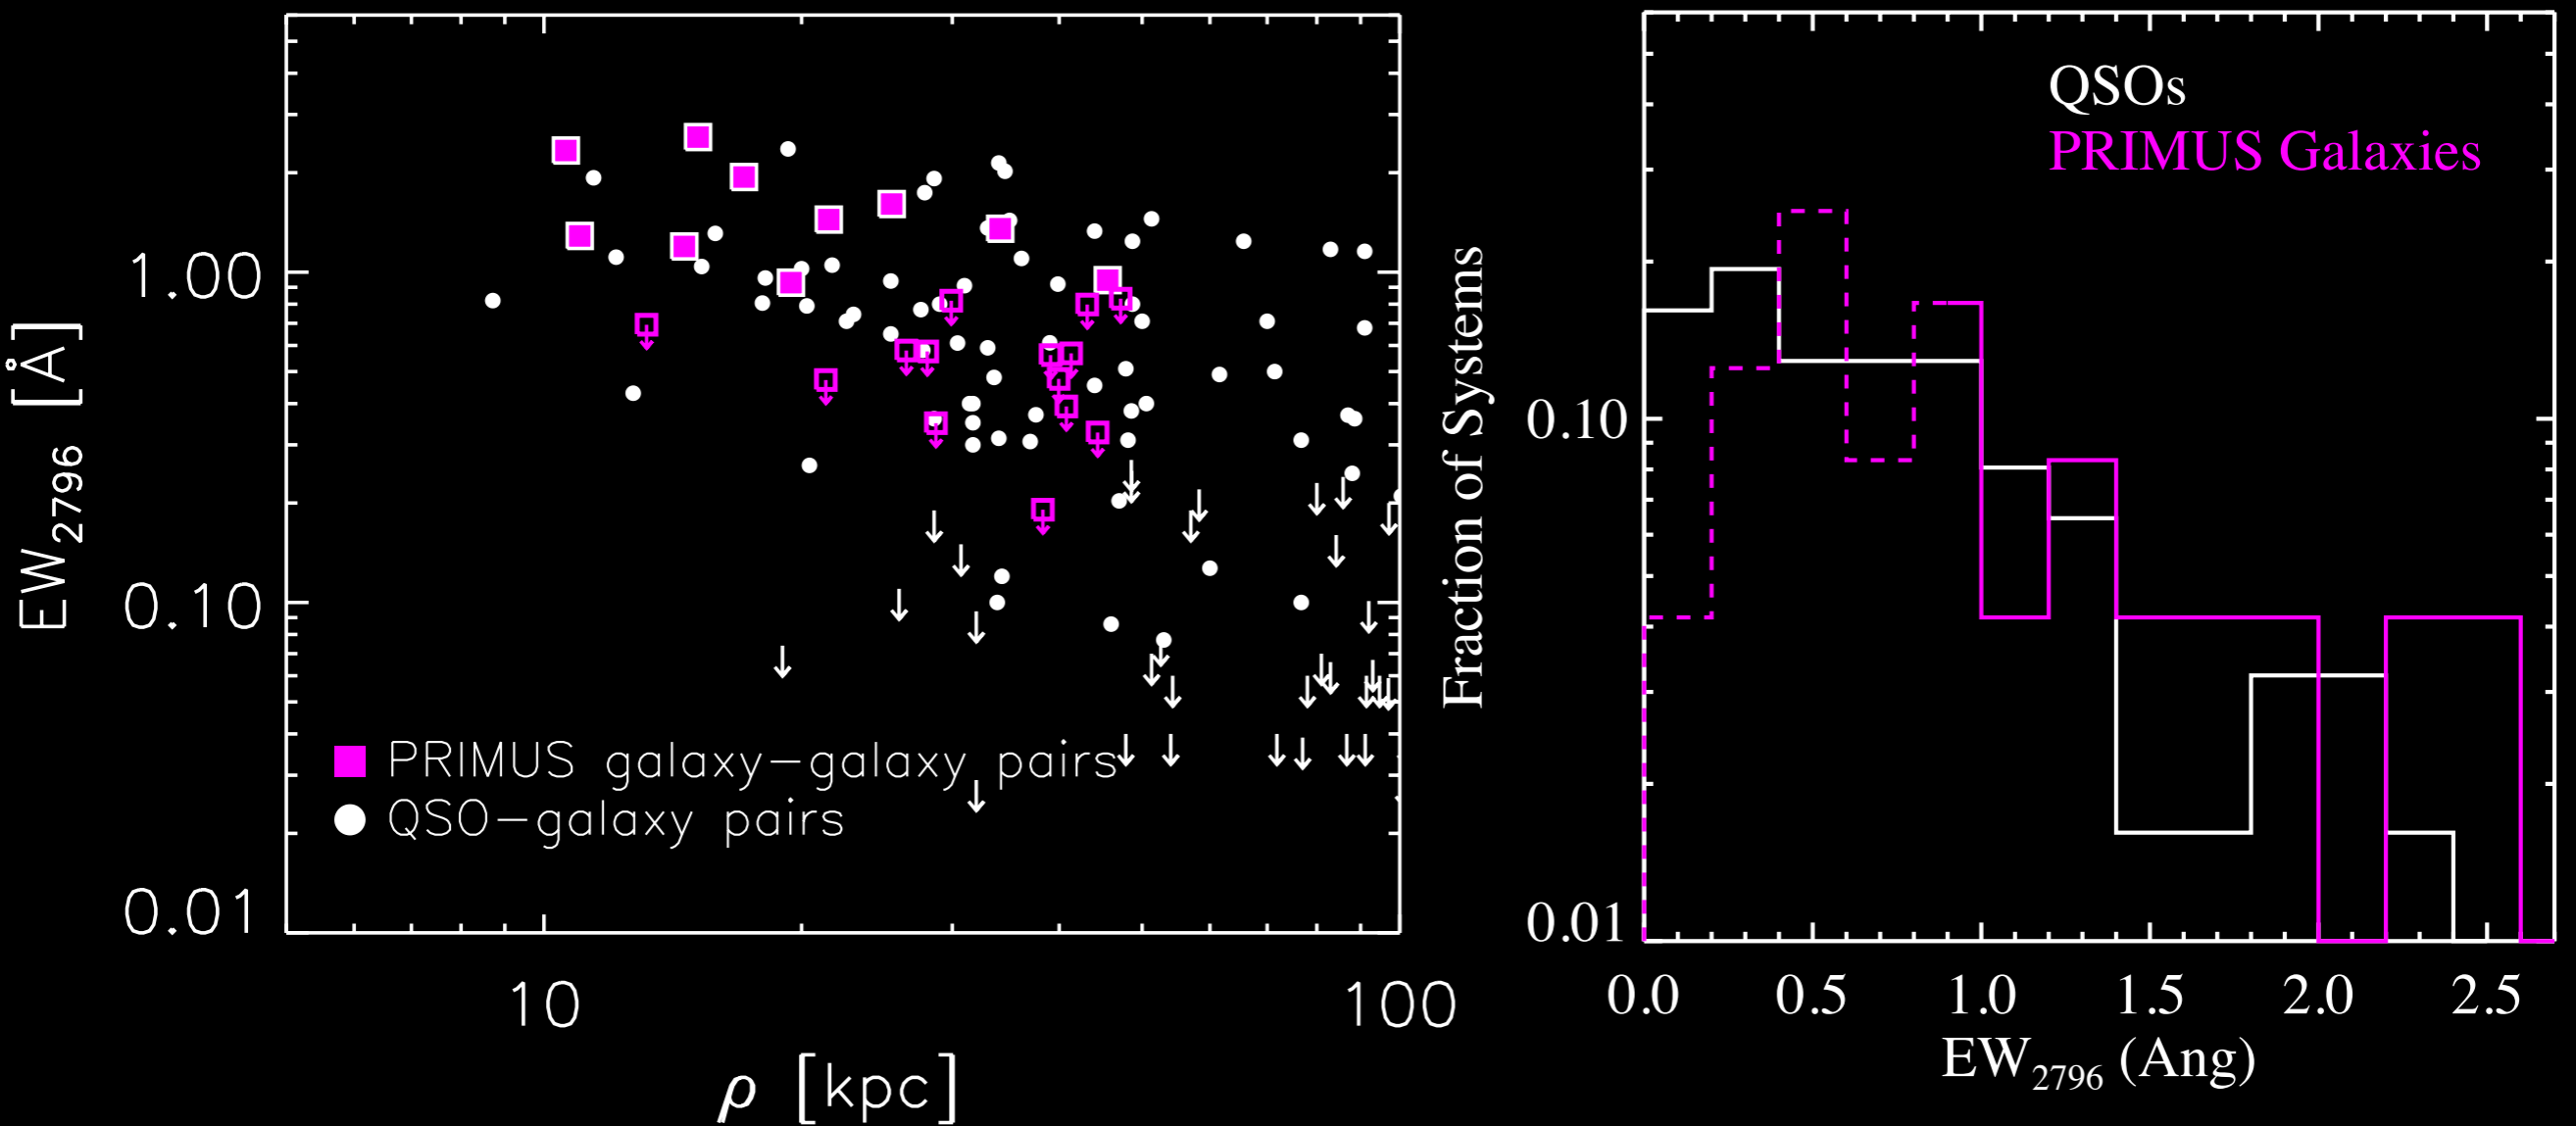

The MgII-absorbing CGM, but with background galaxy beams.

The MgII-absorbing CGM, but with background galaxy beams.

The MgII-absorbing CGM, but with background galaxy beams.

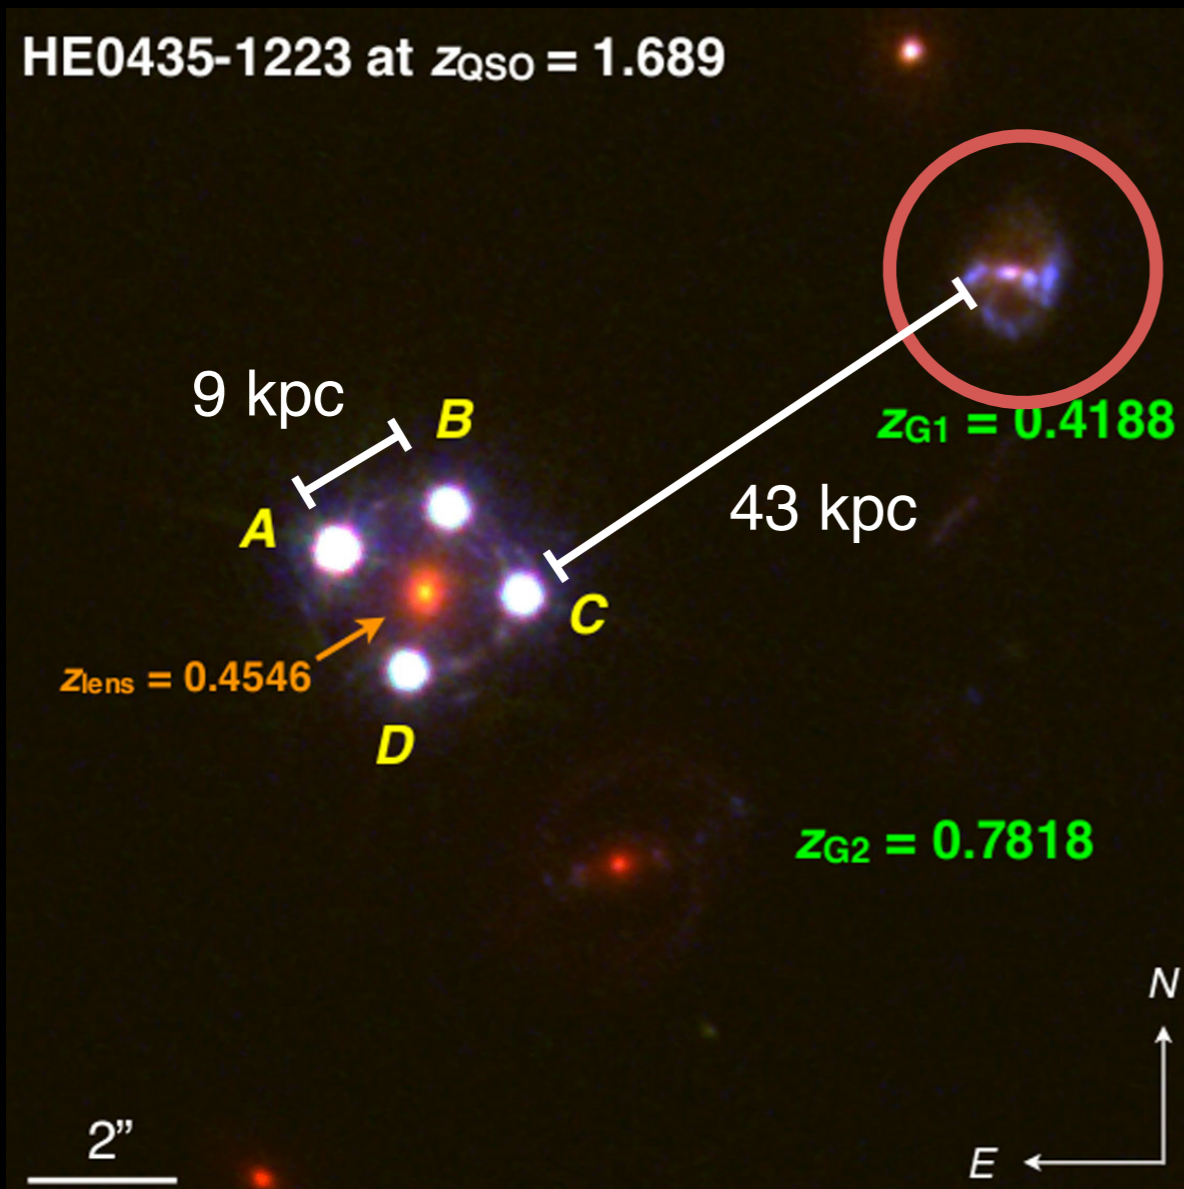

And, photoionization modeling of low-z absorbers yields consistent sizes

Werk et al., yesterday

(but see also Crighton et al. 2014, Prochaska & Hennawi 2009...)

Lensed QSOs offer complementary constraints:

And, these structures are on the verge of being resolved...

If $N(\text{MgII}) > 10^{14} \text{ cm}^{-2}$

At solar metallicity (and with no ionization correction)

$N(\text{H}) > 10^{18.5} \text{ cm}^{-2}$

If cloud is 1 kpc^3 , $M_{\text{cloud}} \sim 2.5 \times 10^4 M_{\text{sun}}$

$10^{12} M_{\text{sun}}$ FIRE halos have particle mass of $\sim 10^4 M_{\text{sun}}$
(Hopkins, Keres, Onorbe, CAFG et al. 2014)

Conclusions

1. Background galaxies offer some of the first direct constraints on the size of cool CGM “clouds”

2. They are coherent over > 1 kpc (within 50 kpc of bright galaxies)
